Introduction

Monitoring breeding birds, the JMBB program

In addition to the 10–12 million of migratory birds, the Wadden Sea also supports large numbers of breeding birds. For several breeding bird species like eurasian spoonbill, oystercatcher, avocet, kentish plover, common redshank, lesser black-backed gull, gull-billed tern and sandwich tern, the Wadden Sea is among the most important breeding sites in Northwest-Europe. Several species are included in Annex I of the EU-Bird Directive or listed as Species of European Concern (SPEC). At national level, many Wadden Sea breeding birds represent an important share of national breeding bird populations and are listed as Red List species.

Monitoring of breeding birds in the Wadden Sea has been carried out by the Joint Monitoring Group for Breeding Birds (JMBB) in the framework of the Trilateral Monitoring and Assessment Program (TMAP) since 1991 (Fleet et al., 1994; Melter et al., 1997; Rasmussen et al., 2000; Koffijberg et al., 2006). The monitoring scheme currently focuses on 35 bird species that are considered characteristic for the Wadden Sea ecosystem. Common breeding birds (8 species) are counted annually in 103 representative census areas evenly distributed over all regions and habitats of the Wadden Sea Cooperation Area. Colonial and rare breeding birds (27 species) are difficult to survey with census areas and are counted by annual complete counts in the entire Wadden Sea. Once every 5 years, a total count of all species, including common species, is carried out (1991, 1996, 2001, 2006, interval now changed to once every 6 years). The monitoring scheme aims to assess and detect population size, distribution and population trends in Wadden Sea breeding birds. Fieldwork is standardised and carried out according to trilaterally harmonised methods (Hälterlein et al., 1995) by nearly 500 ornithologists, mainly consisting of staff of NGOs, governmental bodies, site managers and volunteers. A so-called Quality Assurance Meeting (QAM) is organised regularly to provide a platform for exchange of field experience among counters and discussion of specific counting pitfalls (e.g. Blew, 2003).

This progress report aims to present a regular update of trends in breeding bird numbers, for those species were trend calculations are possible (at the moment 26 species) and that have been monitored from 1991 onwards. Trends, methods, an overview map of census sites and important references about monitoring of breeding birds you can find here as latest version June 2011.

Methods and Acknowledgements

Introduction

As part of the JMBB program, 34 breeding birds species are monitored in the Wadden Sea, of which 26 are presented here with overall and national trends (the other species are too rare to allow trend calculations). Trends are shown for (1) the Wadden Sea as a whole, (2) The Netherlands (3) the federal states of Niedersachsen/Hamburg (Germany), (4) the federal state of Schleswig-Holstein (Germany) and (5) Denmark, see the page 'Counting sites' for an overview of counting sites.

Data and methods

For each year, data on rare and colonial birds are summarized for 56 census regions in the international Wadden Sea. Trend calculations are based on the totals of these census regions within each country or the Wadden Sea as a whole. For common species, numbers are summarised for 103 representative sample sites. Again, trends are calculated at country-level or for the whole international Wadden Sea. On few occasions where a sample plot was not counted in a certain year, data are imputed by the commonly used TRIM package (Trends and Indices in Monitoring data; Pannekoek & van Strien, 1999). Furthermore, TRIM was used to calculate trends. Trends are tested with a Wald-test for significance at P = 0.05, and presented as an index, where 1996 is set at 100. Thus, all indices show population changes relative to 1996. For presentation of the monitoring data, a standardized trend classification is used (similar to that in migratory birds) Fieldwork for breeding birds is carried out by a large number of people, including staff from

Table 1 Trend classification

Trend classifi- cation	Trend description	Population change
11	strong increase	sign. increase of >5% per year
1	moderate increase	sign. increase of <5% per year
-	stable	no significant population change
-	moderate decrease	sign. decrease of <5% per year
11	strong decrease	sign. decrease of >5% per year
-	uncertain	no reliable trend classification possible (mostly due to strong fluctuations)
	data do not allow tren	nd analysis

Summary of trends expressed as indicators

In all habitats concerned (saltmarsh, dunes, beach & outersands and coastal grassland) about 60% of the breeding bird species are in moderate decline. Dunes are the only habitat where steep

declines occur (period 2000-2009). Among all habitats, saltmarshes have the highest proportion of declining species (>80% of all species).

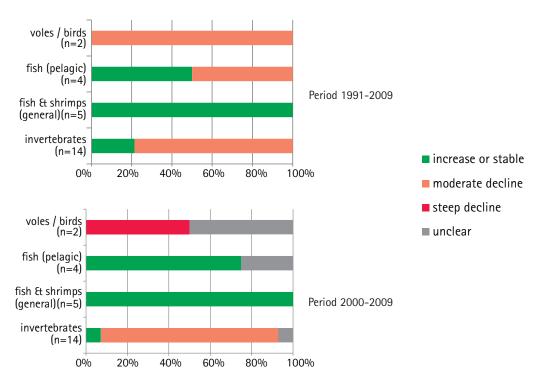

Figures 1-2 Differences in trend status in dependence of habitats for the periods 1991-2009 (left) and 2000-2009 (right)

Large differences in trend status in dependence of food choice exists. In breeding birds species depending on fish and shrimps (mainly Great Cormorant and Eurasian Spoonbill) are doing much better than species depending on inver-

tebrates which show mixed fortunes. Breeding birds feeding on invertebrates and showing declines can be found at saltmarshes, tidal areas and agri-cultural grasslands.

Figure 5
Summary of trends in breeding birds in the Wadden Sea
1991–2009. Shown is the mean annual population change in %, ranked from increasing species (top) to decreasing species (bottom), and based on the output of the TRIM-analysis. Dunlin, Ruff and Common Snipe have become so rare that their annual decline was arbitrarily set at -15%.

A summary of trends for all species for which trends could be calculated (29 out of the 35 monitored species) shows that 15 species have significantly decreased since 1991, among them typical Wadden Sea breeders such as Kentish Plover, Great Ringed Plover, Hen Harrier, Avocet, Common Tern, Common Redshank, Oystercatcher and Common Eider. Dunlin, Ruff and Common Snipe already went down before the monitoring in the Wadden Sea started, and meanwhile have become so rare and scattered breeders that an analysis of their trend after 1991 is not possible. Among the thriving species are mainly colonial breeding birds, like Mediterranean Gull (a 'new' species that is currently expanding its breeding range), Great Cormorant, Eurasian Spoonbill, Great Black-backed Gull and Lesser Blackbacked Gull.

breeding population relative

DK: Skarv

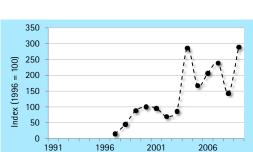

NL: Aalscholver D: Kormoran

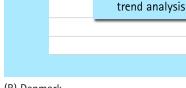

(A) Overall trend in the International Wadden Sea

Explanatory Note

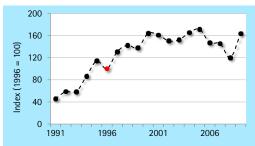

Great Cormorant although only a small part of the NW-European population is breeding in the Wadden Sea, the species is still increasing. This is in contrast with numbers outside the breeding season, which mainly originate from the large inland colonies, where numbers tend to stabilize. Recent developments in Niedersachsen, however, also show declines in breeding numbers. The Netherlands and Niedersachsen support the largest colonies. Schleswig-Holstein (1997) and Denmark (2003) were colonized later on. Nearly all colonies are situated at islands or artifical offshore structures (platforms, etc.).

Figures 8-11 The figures represent the trends of Great Cormorant in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

01440

Platalea leucorodia

DK: Skestork

NL: Lepelaar

(A) Overall trend in the International Wadden Sea

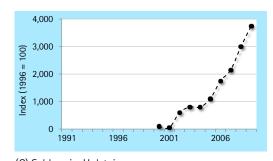

Explanatory Note

In line with the numbers outside the breeding season, Eurasian Spoonbill experienced strong increase in all parts of the Wadden Sea. Since the area was initially colonized from The Netherlands, highest numbers still breed west of the River Elbe. Schleswig-Holstein was colonised in 2000, Denmark in 2007. Further increases are expected, although in The Netherlands also signs of saturation appear. Colonies are mainly found at the islands, both in dune areas and on salt marshes.

total count of Common Shelduck in the interna-

DK: Gravand

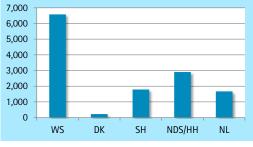

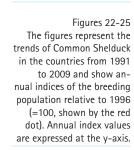

(A) Overall trend in the International Wadden Sea

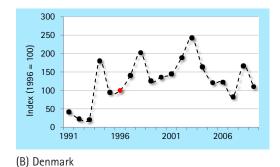

Explanatory Note

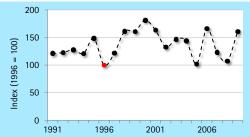

Overall numbers of Common Shelduck have remained stable over the years. In Schleswig-Holstein and Denmark, the species has increased. Especially in Niedersachsen and The Netherlands, recent numbers suggest a decline, but further monitoring is necesarry to confirm this. Shelduck is also a notorious difficult species to monitor due to large numbers of non-breeders and the large distances parents move with their offspring. Hence some fluctuations are probably due to census problems. The species is mainly breeding in rabbit holes (dunes areas) and in e.g. deserted buildings (mainland).

2006.

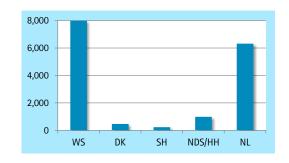

Somateria mollissima

DK: Ederfugl

D: Eiderente

NL: Eidereend

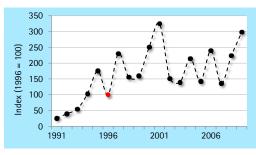

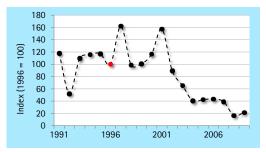

(A) Overall trend in the International Wadden Sea

Explanatory Note

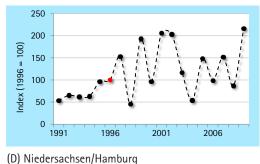

The trend in Common Eider is dominated by The Netherlands, where largest part of the Wadden Sea population is breeding. Nests are mainly found in dune areas. The downward trend observed here from the late 1990s onwards was preceded by mass-starvation among wintering Eiders in 1999/2000 and attributed to depletion of mussel stocks by shellfish fisheries. Small populations in the Danish and Niedersachsen part of the Wadden Sea fluctuate from year to year, but point at an increase. As the species is difficult to monitor due to its breeding behaviour, some fluctuations might also reflect census problems.

Figures 29-32
The figures represent the trends of Common Eider in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Red-breasted Merganser

Mergus serrator

02210

DK: Toppet Skallesluger D: Mittelsäger NL: Middelste Zaagbek

(A) Overall trend in the International Wadden Sea

Explanatory Note

Red-breasted Merganser is only breeding in small numbers in the Wadden Sea, where it reaches the southern edge of its breeding range. Numbers fluctuate, but have increased over a longer term. Core breeding areas are situated in Schleswig-Holstein. In other parts of the Wadden Sea it is an accidental breeder.

Figures 34-35 The left figure represent the trend of Red-breasted Merganser in the international Wadden Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis. The right figure shows the total count of Red-breasted Merganser in the international Wadden Sea and in the countries in 2006.

Figures 36-39
The data about Redbreasted Merganser allow no trend analysis in the countries.

Hen Harrier

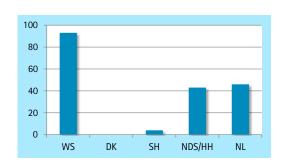

02610

Circus cyaneus

DK: Blå Kærhøg D: Kornweihe NL: Blauwe Kiekendief

Figures 41-42
The left figure represent the trend of Hen Harrier in the international Wadden Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis. The right figure shows the total count of Hen Harrier in the international Wadden Sea and in the countries in 2006.

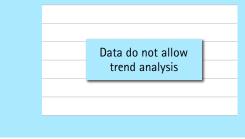

(A) Overall trend in the International Wadden Sea

Explanatory Note

Breeding in Hen Harrier is restricted to The Netherlands and Niedersachsen, where it mainly inhabits the dune areas on the islands. In The Netherlands an ongoing decline has been observed from 1994 onwards. In Niedersachsen the species initially was able to maintain a high population level (resulting in an overall increase). However, recently, numbers are also going down here. A collaborative ringing programme and research on feeding ecology has been set up in both countries to unravel backgrounds for the decline.

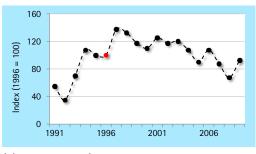

Figures 43-46
The figures represent the trends of Hen Harrier in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Eurasian Oystercatcher

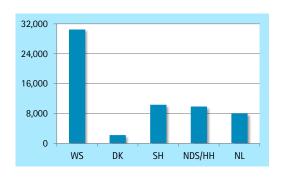

Haematopus ostralegus

04500

DK: Strandskade

D: Austernfischer NL: Scholekster

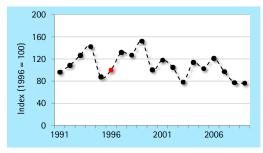

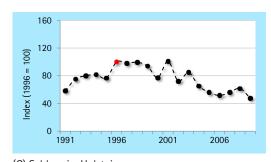

(A) Overall trend in the International Wadden Sea

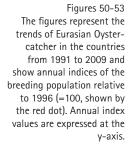

Explanatory Note

Oystercatcher is one of the most abundant breeding birds in the Wadden Sea and a large proportion of the NW-European breeding population can be found here. Long term trends point at declines, especially in The Netherlands and Schleswig-Holstein (other sections have shown stable numbers so far). The decline was initiated by the cold winter 1995/96 and low food stocks, as a result of depletion mainly by shellfish fisheries in the 1990s (in The Netherlands). Although fishery regulations meanwhile have changed, a population recovery has not occurred so far. Research has shown that the species has suffered from increased storm tides in the breeding season. Results from the new parameter breeding succes point at ongoing low reproduction rates in large parts of the Wadden Sea, suggesting further declines in near future.

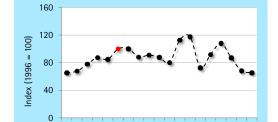

Figures 48-49 The left figure represent the trend of Eurasian Oystercatcher in the international Wadden Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis. The right figure shows the total count of Eurasian Oystercatcher in the international Wadden Sea and in the countries in 2006.

Sea and in the countries in

2006.

Recurvirostra avosetta

DK: Klyde D: Säbelschnäbler

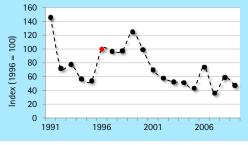

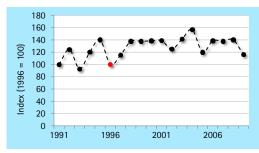

(A) Overall trend in the International Wadden Sea

Explanatory Note

Avocet is one of the prime breeding bird species in the Wadden Sea, supporting a large share of the NW-European breeding population. The overall population shows a decline from 1999 onwards, being most pronounced in The Netherlands and Niedersachsen. In Schleswig-Holstein on the other hand, numbers have remained stable, whereas in Denmark initial declines has partly been reversed recently (resulting in a fluctuating trend). Due to its preference for silty mud flats, Avocet mainly breed on the mainland coast, where they locally suffer from high predation rates by mammalian predators. Besides, the species is susceptible to cold and stormy weather in the chick-rearing period in May and June, affecting chick survival.

Figures 57-60 The figures represent the trends of Pied Avocet in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Wadden Sea and in the

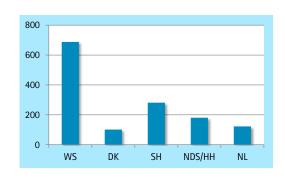

countries in 2006.

DK: Stor Præstekrave

D: Sandregenpfeifer

NL: Bontbekplevier

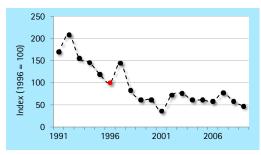

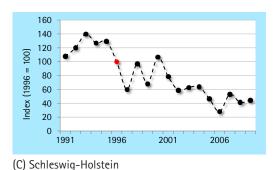

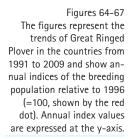

(A) Overall trend in the International Wadden Sea

Explanatory Note

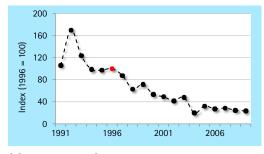

Great Ringed Plover is among the most declining breeding bird species in the Wadden Sea, notably in Denmark, Schleswig-Holstein and Niedersachsen. In The Netherlands the trend has remained stable, although recent numbers are on a lower level than in the 1990s and tend to go down recently. The decline in the Wadden Sea coincides with declines elsewhere in the breeding range. In the Wadden Sea, losses have been often attributed to disturbance and reduced habitat dynamics on the preferred breeding sites at the beaches and lower dunes.

Figures 69-70
The left figure represent the trend of Kentish Plover in the international Wadden Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis. The right figure shows the total count of Kentish Plover in the international Wadden Sea and in the countries in 2006.

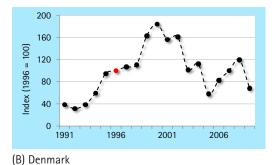

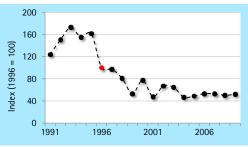

(A) Overall trend in the International Wadden Sea

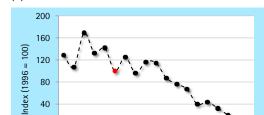

Explanatory Note

The Wadden Sea represents the core breeding area for Kentish Plovers in NW-Europe. Ongoing declines have been observed from the mid 1990s onwards. Only in Denmark, the species is still thriving at islands like Rømø. The decline in other parts of the Wadden Sea seems to level off recently, but this has to be confirmed by future monitoring. Declines have not only been reported in the Wadden Sea, but also elsewhere in the breeding range. In the Wadden Sea, the species has faced limited habitat dynamics in coastal habitats (beaches and lower dunes) and increased disturbance by tourism.

Figures 71-74
The figures represent the trends of Kentish Plover in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

NL: Wulp

Eurasian Curlew

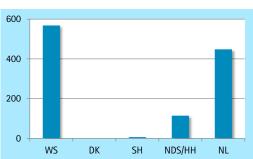

Numenius arquata

05410

DK: Stor Regnspove

D: Großer Brachvogel

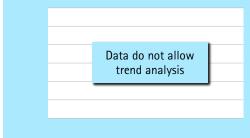

(A) Overall trend in the International Wadden Sea

Explanatory Note

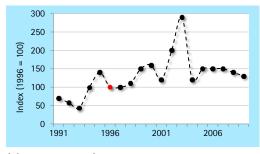

Eurasian Curlew is a typical dune-breeding species in the Wadden Sea. Hence, it is mainly confined to the islands, especially those west of the River Elbe. The species is in decline, mainly due to losses in The Netherlands, where highest densities occur. This development has been attributed to vegetation succession in coastal dunes and negative impact of outdoor recreation. At the same time, birds have shifted from coastal dunes, to agricultural areas inland.

Figures 90-91
The left figure represent the trend of Eurasian Curlew in the international Wadden
Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Tringa totanus

DK: Rødben D: Rotschenkel

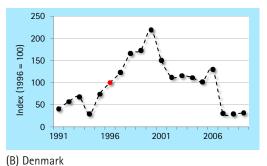

NL: Tureluur

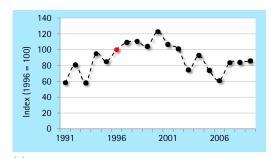

(A) Overall trend in the International Wadden Sea

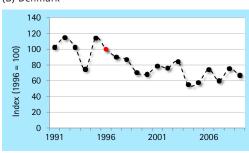

Explanatory Note

Common Redshank preferably breed in salt marsh areas with tall vegetation. The species has experienced declines from the late 1990s onwards, resulting in an overall negative trend. This is mainly due to lower numbers in The Netherlands and Niedersachsen, whereas in Denmark and Schleswig-Holstein trends have remained stable over the years. Recent counts in Niedersachsen and The Netherlands point at a partial population recovery, but future counts have to confirm if this development is sustaining.

Figures 99-102
The figures represent the trends of Common Redshank in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Wadden Sea and in the

countries in 2006.

DK: Sorthovedet Måge D: Schwarzkopfmöwe NL: Zwartkopmeeuw

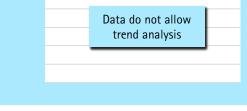

(A) Overall trend in the International Wadden Sea

Explanatory Note

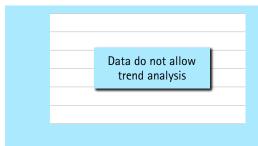

Mediterranean Gull is a rather new breeding species to the Wadden Sea, and in line with developments in e.g. the Delta area, SW-Netherlands, numbers and distribution have also expanded in the Wadden Sea (though not as fast as elsewhere). In 1991 the species was only found in The Netherlands, in 1994 it colonized Niedersachsen and in 1996 Schleswig-Holstein and Denmark. Recent counts suggest that numbers are stabilizing. The largest colony is found on an island in the River Elbe. Elsewhere mainly scattered pairs are found breeding, often also associated with colonies of Black-headed Gull.

Figures 106-109 The figures represent the trends of Mediterranean Gull in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Common Black-headed Gull

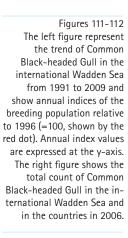

05820

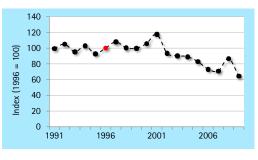

Larus ridibundus

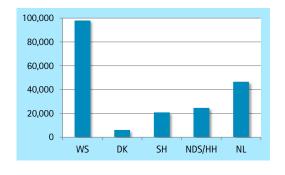

DK: Hættemåge

D: Lachmöwe

NL: Kokmeeuw

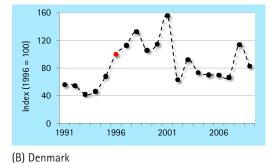

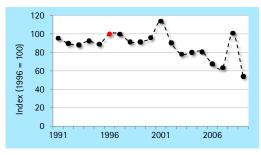

(A) Overall trend in the International Wadden Sea

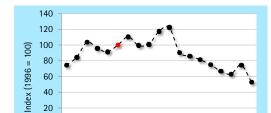

Explanatory Note

Black-headed Gull is one of the most abundant breeding birds in the Wadden Sea and a major part of the NW-European population is found here. Highest numbers breed west of the River Elbe. Largest colonies are situated in salt marshes and on remote islands. Apart from Denmark, declines have been reported all over the Wadden Sea, especially after 2000. Hence, earlier statements that Wadden Sea breeding birds performed better than inland breeding colonies are no longer valid. At least locally, colonies have been abandoned due to predation pressure, but other factors like food availability might affect population trends as well.

Figures 113-116
The figures represent the trends of Common Black-headed Gull in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

The right figure shows the

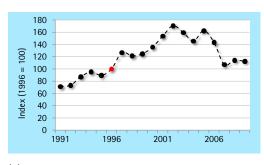

total count of Common Gull in the international Wadden

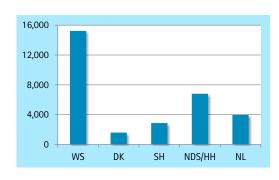

Sea and in the countries in

DK: Stormmåge

NL: Stormmeeuw

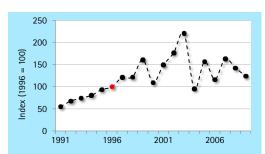

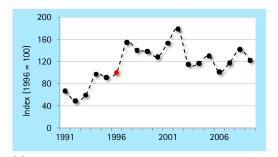

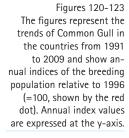

(A) Overall trend in the International Wadden Sea

Explanatory Note

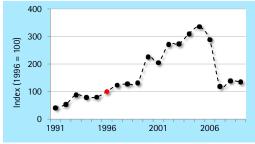

Even if, the Wadden Sea is not a main breeding area for Common Gull in an international context, the species is thriving in most countries, resulting in a positive overall trend. Only in The Netherlands the species is in decline, especially after 2000. Breeding colonies are mainly found in coastal dune areas. It is not precisely known for what reason the population in The Netherlands is doing less well than elsewhere. In some years low reproductive rates have been recorded, but as the species is not part of the breeding success monitoring scheme, it is not known on what scale this occurs.

Lesser Black-backed Gull

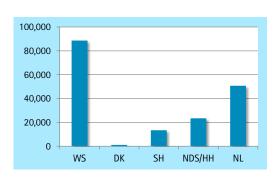

05910

Larus fuscus

DK: Sildemåge D: Heringsmöwe NL: Kleine Mantelmeeuw

Figures 125-126 The left figure represent the trend of Lesser Black-backed Gull in the international Wadden Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis. The right figure shows the total count of Lesser Blackbacked Gull in the international Wadden Sea and in the countries in 2006.

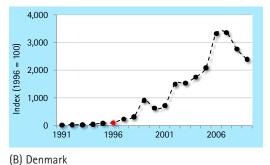

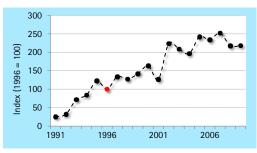

(A) Overall trend in the International Wadden Sea

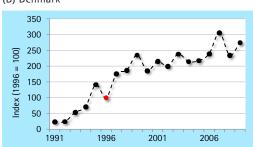

Explanatory Note

Lesser Black-backed Gull is among the fastest expanding species in the Wadden Sea. Recent counts in Denmark, Schleswig-Holstein and Niedersachsen point at possible declines. Data from the breeding success monitoring in The Netherlands show high chick mortality due to limited food provision. Hence, the increase observed so far might reverse in a drop in numbers, but this has to be confirmed by further counts and continued monitoring of breeding success. In an international context, a large proportion of the NW-European population is breeding in the Wadden Sea.

Figures 127-130
The figures represent the trends of Lesser Black-backed Gull in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Herring Gull

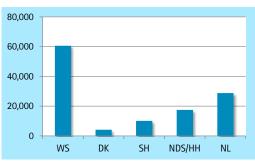

Larus argentatus

05920

DK: Sølvmåge

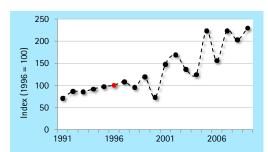

Figures 132–133
The left figure represent the trend of Herring Gull in the international Wadden Sea from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

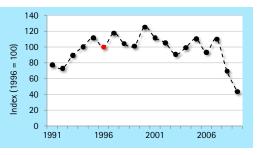

The right figure shows the total count of Herring Gull in the international Wadden Sea and in the countries in 2006.

(A) Overall trend in the International Wadden Sea

Explanatory Note

Herring Gull often breeds in mixed colonies with Lesser Black-backed. Compared to the latter species, it feeds more extensively on the mud flats in most areas. Populations have declined in the whole Wadden Sea, mainly due to losses in The Netherlands and Niedersachsen, which are the core breeding areas. In The Netherlands the species has suffered from depletion of mussel stocks by shellfish fisheries. Moreover, they have benefited from rubbish dumps earlier, which today are all closed and not available as food resource anymore. The smaller populations in Denmark and the colonies in Schleswig-Holstein are performing better, and especially in Denmark have shown a strong increase.

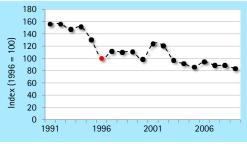

Figures 134-137
The figures represent the trends of Herring Gull in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Wadden Sea and in the

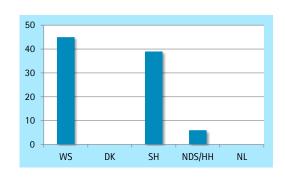

countries in 2006.

DK: Sandterne

D: Lachseeschwalbe

NL: Lachstern

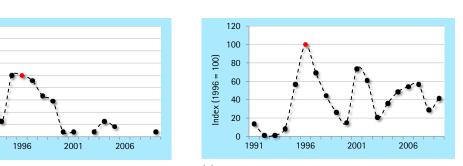

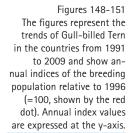

(A) Overall trend in the International Wadden Sea

Explanatory Note

The Wadden Sea represents the only breeding area for Gull-billed Terns in the Wadden Sea. Initially this was confined to Denmark, but since the 1970s this has shifted to Schleswig-Holstein, where the species is currently breeding in a colony in Neufelder Koog in the Elbe estuary, associated with Black-headed Gull, Common Tern and Arctic Tern. Earlier settlements in the Niedersachsen part of the Elbe estuary have been deserted now. Due to fluctuating numbers, the overall trend is not clear, although current numbers are lower compared to the 1990s.

to 2009 and show an-

DK: Fjordterne

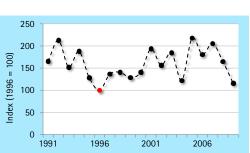

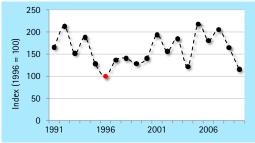

(A) Overall trend in the International Wadden Sea

Explanatory Note

Breeding Common Terns are widespread in the Wadden Sea and inhabit different habitats, including harbour areas, rooftops of buildings and other anthropogenic habitats. The species is only doing well in Schleswig-Holstein, whereas in other countries populations have gone down, especially in Denmark. Hence, overall trend is negative. Often, poor food availability has been put forward as main background for declines, but other factors as predation pressure (mainland colonies), reduced habitat dynamics and losses due to storm tides in the breeding season are probably operating as well.

Sterna paradisaea

DK: Havterne D: Küstenseeschwalbe NL: Noordse Stern

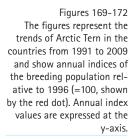

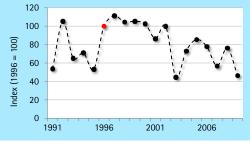

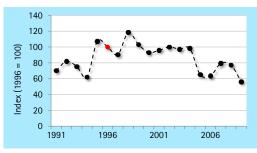

(A) Overall trend in the International Wadden Sea

Explanatory Note

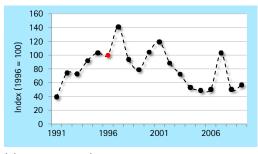

Arctic Tern has a more northernly breeding range in Europe and therefore largest colonies are found north of the River Elbe. Large colonies are mainly situated in Schleswig-Holstein. Compared to Common Tern (where it sometimes associates with), they prefer more sparsely vegetated breeding sites and are found less in anthropogenic habitats. Apart from Denmark, populations in all parts of the Wadden Sea have decreased. This trend is most pronounced in the westernmost breeding sites in The Netherlands and Niedersachsen and mainly occurred in from the late 1990s onwards.

DK: Dværgterne

D: Zwergseeschwalbe

NL: Dwergstern

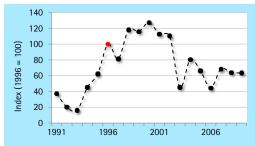

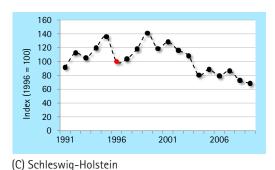

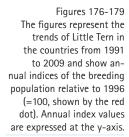

(A) Overall trend in the International Wadden Sea

Explanatory Note

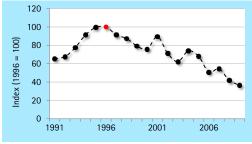

Little Tern predominantly breeds on the islands, where it inhabits beaches, sand pits and primary dunes. At many sites, protective measures are taken to keep colonies undisturbed from public. After an initial increase in the 1990s, the species is showing negative trends in the past decade, leading to an overall stable trend classification. However, in Schleswig-Holstein and Niedersachsen, both supporting core breeding sites, significant declines have occurred. In Denmark (increase) and The Netherlands (stable) populations show more annual variation in numbers.

Annual index values are expressed at the y-axis. The right figure shows the total count of Short-eared Owl in the international Wadden Sea and in the countries in 2006.

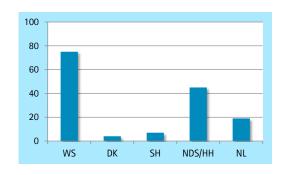

Asio flammeus

DK: Mosehornugl

D: Sumpfohreule

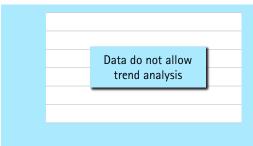

(A) Overall trend in the International Wadden Sea

Explanatory Note

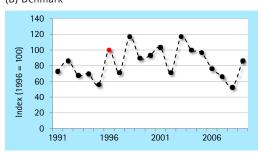

Short–eared Owls prefer open dunes and heathland as breeding habitat, often in association with feeding areas in grassland or salt marshes. It has its strongholds west of the River Elbe and its distribution is mainly confined to the islands. The overall trend is classified as stable, but tends to decline recently. Especially in The Netherlands the species has suffered major losses and is on the brink of extinction. In Niedersachsen, it was able to keep population stable (compare Hen Harrier), but here a decline started in 2003.

Figures 183–184
The figures represent the trends of Short-eared Owl in the countries from 1991 to 2009 and show annual indices of the breeding population relative to 1996 (=100, shown by the red dot). Annual index values are expressed at the y-axis.

Total Counts Rare Species

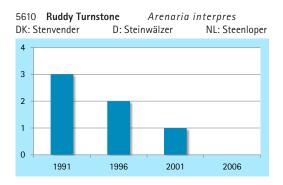

For 7 breeding bird species of the JMBB program data do not allow trend analysis. Nevertheless, to give an impression on numbers of these bird species the total count numbers are given.
